The Use of Patient-Specific Implants in Oral and Maxillofacial Surgery

Michael F. Huang, DDS, MD^{a,b,*}, David Alfi, DDS, MD^{a,b}, Jonathan Alfi, MA^c, Andrew T. Huang, MD^d

KEYWORDS

- Patient-specific implants • 3D printed plates
- Custom temporomandibular joint total joint replacement • Maxillofacial reconstruction
- Orthognathic surgery • Computer-aided design • Computer-aided manufacture

KEY POINTS

- Patient-specific cutting guides and patient-specific implants are becoming increasingly common in oral and maxillofacial surgery.
- Custom temporomandibular joint (TMJ) total joint prosthesis allows for individualized reconstruction of the TMJ.
- Computer-aided design and computer-aided manufacturing technology allows for the fabrication of patient-specific cutting guides and patient-specific reconstruction plates used for accurate and efficient reconstruction of complex maxillofacial defects with or without vascularized bone flaps.
- Improved accuracy of patient-specific implants allows for their application in orthognathic surgery, although their use in mandibular surgery, specifically the bilateral sagittal split osteotomy, has yet to be proven.

INTRODUCTION

Personalized medicine is a term that has gained momentum in the twenty-first century. The National Cancer Institute defines it as “a form of medicine that uses information about a person’s gene, proteins, and environment to prevent, diagnose, and treat disease.”¹ It refers to a shift away from the “one-size-fits-all” approach designed for the average patient toward treatments tailored for the individual. Given the complexity of the facial skel-

design and computer-aided manufacturing (CAD/CAM) technology, several recent developments have allowed the application of personalized medicine to oral and maxillofacial surgery in order to improve outcomes. The decreasing cost of this technology has also made it more affordable and accessible to patients. Patient-specific implants are currently used in multiple areas of oral and maxillofacial surgery, including temporomandibular joint (TMJ) total joint replacement, reconstruction of the maxillofacial skeleton, and orthognathic surgery.

Significant variation of the temporomandibular joints with the shallow articular fossae and flat mandibular head bilaterally with significant narrowing of the articular joint space. The intra-articular disc is visualized bilaterally with the normal alignment during open and closed positioning. There is no joint effusion.

doesn't have Instagram and said "wow he did a fantastic job"

Hi, thanks for contacting us. We've received your message and appreciate you reaching out. Due to the volume of questions we may not reply immediately. If you have any questions call 713-489-6984. Also please don't Include any personal medical information in this tool - we can also not provide any personal medical Communication on IG.

If she never told me about it I would've never of guessed she has surgery

She looks amazing !

Thank you for this message and pic and please say hi

CC: left TMJ pain

HPI: The patient is a 55-year-old woman who has had left TMJ problems for 13 years. She has managed her symptoms with an orthotic, until 3 months ago when she got worse. Now, she has daily. The pain is episodic, sometimes happening while at rest, other times when talking, or when chewing. The pain is severe is localized in the left temple, and left masseter, radiating, over the head, to the contralateral temple.

In addition to the pain, the patient has had intermittent locking (closed) of the left TMJ. She always been able to unlock her joint , by manipulating it.

X-RAYS: CBCT TMJs: Severe degenerative changes in the TMJs, left worse than right. On the left, there is significant condylar erosion, with irregular articular surface and significantly decrease joint space. On the right, the condyle has a large pseudocyst and some osteophytes.

ASSESSMENT:

1. Severe left TMJ osteoarthritis, with severe arthralgia
2. Moderate to severe right TMJ osteoarthritis, with mild arthralgia

PLAN:

1. Kenalog injection in the left TMJ, under sedation
2. The patient may need a total joint replacement

Tissue Exam: S20-03276

Status: Final result
Visible to patient: No (Not Released)
Next appt: None

Component

Final Diagnosis

Bone, left mandible, excision:

- Features most consistent with juvenile aggressive (active) ossifying fibroma of jaw.
- Closest margin is lateral with tumor at 0.5 mm from the inked margin.

I have reviewed the material described and edited this report.

Abstract

Reconstruction of large segmental mandibular defects presents a challenge for oral and maxillofacial surgeons, particularly in the skeletally immature pediatric patient. Autogenous bone graft is historically preferred; however, harvest of autograft requires a second surgical site, risking donor-site complications as well as the potential for long-term complications in the growing child. Here, we present the first known report of a pediatric patient who underwent immediate mandibular reconstruction of a 6.5-cm long segmental defect using a cellular bone allograft (VF-CBA) combined with custom-fabricated guides and plates following tumor resection. The use of VF-CBA, along with the custom guides and plates, eliminated the need for autograft harvest in a child, enabled an entirely intraoral approach, avoiding the creation of a cutaneous scar, and reduced the total operative time, resulting in a fast recovery and improved patient satisfaction. By 7 months

USING THE RIGHT TOOLS

- Faster surgical time
 - Faster recovery
 - Morbidity
 - Avoid Donor Site
- Stronger
 - Avoid hardware failure
 - Supports interpositional graft like ViviGen
- More direct transfer of information
 - Less error
 - Splint-less
- Optimize Movements
 - Not limited by standard designs
 - Confidence in grafting
- Avoiding Complications
 - Unsightly scars
 - Nerve injury
 - Bleeding
